

Chemical Technology
Prof. Indra D. Mall
Department of Chemical Engineering
Indian Institute of Technology, Roorkee

Module - 5
Fermentation
Lecture - 1
Sugar and Fermentation Industry

We are discussing organic chemical technology course, and we have discussed module 1, module 2, module 3 and module 4 of this course. Today will be discussing module 5 and which will comprise sugar and fermentation industry, especially the alcohol, which we are getting from the molasses, which we are getting from the sugar plant.

(Refer Slide Time: 00:57)

Coverage of the lecture

- Introduction of sugar industry
- Historical review of sugar Industry
- Profile of Sugar Industry
- Process Steps in Sugar Manufacture
- By Product from sugar Plant
- Alcohol from Molasses
- Different type of Alcohol
- Alcohol From Biomass

So, the coverage of the lecture that will be introduction of the sugar industry historical review of the sugar industry because this is one of the oldest industry, you can say the then the profile of sugar industry process step in the sugar manufacture byproduct from the sugar plant, alcohol from molasses different type of alcohol, alcohol from biomass.

(Refer Slide Time: 01:21)

Introduction

- Sugar industry is one of the most important agro-based industries in India and has an important impact on rural economy.
- India is the first two largest sugar producing countries in the world sugar production during 2007-08 was 263 lakh. There are 624 sugar factories in the country as on March 31, 2009.

As you know the sugar industry is one of the most important agro based industry in India, and has an important impact on the rural economy. India is the first two largest sugar producing country in the world, with sugar production during 2007-08 was 263 lakh tons, there are 624 sugar factory in the country. As on 31, 2009 sector wise break up is given in other slides.

(Refer Slide Time: 01:56)

Sugar

But this is the importance of the sugar, you are saying the different type of sugar that we are making and the even that they have lot of the changes, in the quality of the sugar

from brown to white. That means, the even from the smaller particle sugar to the cubical more larger size of the crystals. So, these are the different type of the sugar that we are making.

(Refer Slide Time: 02:26)

Different type of Sugar and Alcohol

- **Sugar**
- Gud and Khand, raw sugar , refined sugar,, soft brown sugar, coffe crystal Granulated sugar : larger and smaller size, Sugar Cubes
- **Alcohol**
- Industrial alcohol Absolute alcohol (Anhydrous alcohol)
- Alcoholic beverages: Beers, wines and whisky, Brandy, Liquors

So, different type of the sugar and alcohol sugar, gud and khand, raw sugar because this was the khand, khandsari that was the oldest and that is the you can and the initial stages was there in the development of the sugar industry. And raw sugar, refined sugar, soft brown sugar, coffee crystal granulated sugar, larger and in smaller size sugar, sugar cubes different shapes that we are getting alcohol, alcohol that will be the industrial alcohol, absolute alcohol and anhydrous alcohol that we are making alcoholic beverages and beers, wines, whisky, brandy, liquors different type of the alcohol beer because that from the ancient time, we have been using the alcoholic beverage. Let us discuss about the historical review of the sugar cane and sugar manufacture in India.

It is universally acknowledged that India is the home land of the sugar cane and sugar. The reference of the sugarcane cultivation, its crushing, and preparation of the gur in Atharva veda as well as Kautaliya, Arthasatra that has been reported. It is reported as sugar came to India from New Guniea centuries before the Christ. The Indian offering the contain 5 amrits that is the during the any religious function, we use the milk, curd, ghee, honey and sugar, which shows the importance of the sugar in our daily life. And sometimes we also compare mithas that is the sugar, in our daily life.

(Refer Slide Time: 03:23)

Historical Review of Sugar cane and sugar: India

- It is universally acknowledged that India is the homeland of sugar cane and sugar.
- There references of sugarcane cultivation, its crushing and preparation of Gur in Atharva Veda as well Kautaliya's Arthasastra
- It is reported that sugar came to India from New Guinea centuries before Christ.
- The Indian offerings contain five amrits: Milk Curd, Ghee, Honey and Sugar which shows importance of Sugar

(Refer Slide Time: 04:09)

Historical Review of Sugar cane and sugar: India

- Sugar was made in India during fourth and sixth centuries. Crystal prepared from juice was called Sarkara.
- The word sugar is derivative of Sarkara
- Larger Lumps was called Khand
- It is from India that the art of making sugar spread to Persia and world over.
- First Sugar plant started at Aska in Orissa in 1824

Sugar was made in India during in the fourth and sixth century. Crystals prepared from the juice was called sarkara. The word sugar is derived from the sarkar that the word we are using large, larger lumps was called the khand. It is from India that the art of making sugar is spread to Persia and world over. First sugar plant is started at Aska in Orissa in 1824.

(Refer Slide Time: 04:39)

Historical Review of Sugar cane and Sugar: India

- First vacuum pan process sugar was set up at Saran in Bihar in 1904.
- By 1931-32 there were 31 sugar Mill with total production of 1.5 lakhs tonnes whereas consumption was 12 lakhs tonnes
- 1932: India sugar Industry protection act was promulgated.
- By 1934-35 111 sugar factories producing 4.6 lakhs tonnes
- 1940-41: 148 sugar factories, production: 11 lakh tonnes

The first vacuum pan process sugar was set up at Saran district in Bihar, in 1904. By 1931-32 there was 31 sugar mills with total production of 1.5 lakh tones. Whereas, the consumption was around 12 lakh tones. So, the you can imagine the requirement of the sugar that was there. In 1932 India sugar industry protection act was promulgated and by 1935-34-34, 111 sugar factories producing 4.6 lakhs tones of the sugar came into existence. 1940-41 there were around 148 sugar factory, with production of 11 lakh tones.

(Refer Slide Time: 05:34)

Historical Review of Sugar cane and Sugar: India

- Growth of Indian Sugar Industry after Independence in organised sector after Industrial Policy Resolution in 1948 and industrial act in 1956. and growth of Cooperative sector of sugar Industry after that.
- Latter Establishment of National federation of co-operative sugar factories
- First cooperative sugar factory was Pravara cooperative sugar factory was set up in Maharashtra

Growth of the Indian sugar industry and that was only after the independence, in the organized sector after industrial policy resolution in 1948, and industrial act in 1946 that were there and the growth of the cooperative sector of the sugar industry, after that the lot of the development in the sugar production, and the sugar mill setting of the sugar mill came into existence. Later establishment of the national federation of the cooperative sugar factory was there. And the first cooperative sugar factory was Paravara cooperative sugar factory, which is in Maharashtra. And Maharashtra is also one of the leading sugar producing state in our country. This is the profile of Indian sugar industry and the number of the sugar factory because many of the number that may vary, but this is the figure which we I got by 2012.

(Refer Slide Time: 06:40)

Profile of Indian Sugar industry	
Sector	No. of sugar factories
Private	245
Public	62
Cooperatives	317
Total	624

Source: Business standard April 24,2012

Private sector 245, public sector 62, cooperative 317 and total number of the sugar mill are 624. Capacity is varying very widely, processed technology remaining the same, but lot of the improvement technological development that has been done in the sugar plant and the old sugar mill. If you compare the old sugar mill and the new sugar mill, there is lot of difference in the process technology, regarding the refining of the sugar and also the capacity of the plant.

(Refer Slide Time: 07:17)

Sugar Industry

- In 2010-11, sugarcane was planted in 4.98 million hectares across the country, of which 1 million hectares was in Maharashtra and over 2 million hectares in Uttar Pradesh, official estimates show.

In 2010 and 11, sugar cane was planted in 4.98 million hectares across the country of which 1 million hectares was in Maharashtra, for 2 million hectares in Uttar Pradesh official estimates show. This is the actually we see Maharashtra and UP and Bihar these are the some of the major sugar producing states in India.

(Refer Slide Time: 07:48)

Profile of sugar industry

As per 2010-11	
Area	4.98 million hectares
Cane production	346.00 Million tonnes
Sugar production	24.20-24.50 Million tonnes

Source: Business standard April 24,2012

This is the cane production and sugar production figure as on 2010-11. The total cane production that was 346 million tones sugar production, 24.20-24.50 million tones.

(Refer Slide Time: 08:02)

Sugar Industry

- Uttar Pradesh and Maharashtra are the two largest sugarcane producing states in the country, accounting for more than 80 per cent of the annual crop production.
- India is one of the largest producers of alcohol in the world and there has been a steady increase in its production over the last 15 years, according to fresh statistics.

As I told you that the UP and Maharashtra are the two largest sugar cane producing states in the country, accounting for more than 80 percent of the annual crop production. India is one of the largest producer of alcohol in the world. There has been a steady increase in its production over the last 15 years according to the fresh statistics. Actually, you see the molasses to alcohol conversion. Now, that has become very important in case of and that will be discussing separately. How we are making the molasses and the importance of the alcohol from the molasses in the chemical industry.

(Refer Slide Time: 08:41)

Sugar Industry

- India is a dominant producer of alcohol in the South-East Asian region with 65 per cent of the total shares and contributes to around seven per cent of the total alcohol beverage imports into the region.
- More than two-thirds of the total beverage alcohol consumption within the region is in India, according to figures in the newly compiled *Alcohol Atlas of India*.

India is the a dominant producer of alcohol in South East Asia region, with 65 percent of the total shares, and contributes to around 7 percent of the total alcohol beverage imports into the region. More than two-thirds of the total beverage alcohol consumption, with the region is in India according to the figure in newly compiled alcohol atlas of India.

(Refer Slide Time: 09:09)

Sugar Industry

- There has been a steady increase in the production of alcohol in the country, with the production doubling from 887.2 million liters in 1992-93 to 1,654 million liters in 1999-2000 and was expected to treble to 2300 million liters by 2007-08.
- Sugar industry is highly seasonal industry, with season lengths of about 6-18 weeks for beets and 20-32 weeks for cane [Pollution Prevention hand book, World Bank group July 1998].

There has been a steady increase in the production of alcohol in the country, with the production doubling from 81.2 million liters in 1992-93 to 1.654 million liters in 1999-2000 and was expected to treble to 2300 million liters by 2000. The production actually the data was not available. So, that is more than this what we are having today. Sugar industry is highly seasonal industry.

This is one of the problem in case of the sugar industry with the season lengths of the about 6-18 weeks for beets, and 20 to because beet is also one of the source of the sugar, but it was here. We will be discussing mostly about the sugar and from the sugar to alcohol and 20-32 weeks for the cane. So, processing in the sugar manufacture, what are the various steps involved in case of the. Now, let us discuss this manufacture of the sugar.

(Refer Slide Time: 10:19)

Process Steps in Sugar Manufacture

- **Extraction of Juice:** This involves washing, shredding and extraction of juice from sugar cane by milling
- **Juice Purification:** The extracted juice is purified using lime and CO_2 for removing non- sugar substance from the Juice. Sulphilation using SO_2 is also being used.
- **Concentration of Juice by Evaporation :** Evaporation of the purified juice from 15% sugar content to 65-70% sugar content.

Extraction of the juice, this involves washing shredding and extraction of the juice from sugar cane by milling. Here you find lot of the development that has taken place in milling to increase the extraction of juice from the cane because the overall economic sugar recovery that is one of the very important factor. In case of the economic just to have more and more economic. Next, step after the extraction of the juice the juice purification here also lot of the development earlier it was the carbonation.

Now, we are also having we are using the sulphilation using this SO_2 that is also being used. So, the extractive juice is purified using lime and CO_2 for removing the non sugar substances from the juice sulphilation using SO_2 is also being used. Then the next, step after the juice purification, the concentration of the juice by evaporation, we are having the number of multiple effective operator for evaporation of the purified juice, which we are getting that is around 15 percent. So, that it may be crystallized so, the after the concentration of the juice that is going to from the evaporation, it is going to crystallization.

(Refer Slide Time: 11:52)

Process Steps In Sugar Manufacture

- **Crystallisation:** Crystallisation of concentrated sugar solution to sugar crystal.
- **Centrifugation:** Centrifugal separation of Crystallised sugar. Molasses are left behind after Centrifuging which is used for production of alcohol.
- **Refining of the Raw Sugar:** The raw sugar is dissolved, filter and crystallized again to get high grade refined sugar.

Crystallization of the concentrated sugar solution to sugar crystal here that the crystallization part that is very important, because the growth of this crystal size, that is very important which is keeping. Actually, the product better product quality centrifugation because the separation of the sugar crystal from the molasses, at the residue.

So, centrifuges separation of the crystallize sugar molasses are left behind after the centrifuging, which is used for the production of the alcohol. So, the molasses which is that is one of the very important by product of the sugar manufacture. Then the further refining of the raw sugar, the raw sugar is dissolved filtered and crystallized again to get high grade refined sugar. Let us discuss slightly more detail about the sugar refining part, sugar refining part.

Actually, affination raw sugar mixed with the saturated syrup. Then centrifuged. Surface impurities are dissolve and removed carbonation using milk of lime and CO_2 , removal of impurities color and other impurities, which are present in the juice. Sulphilation process it may be the cold sulphilation, or the sulphilation of the after the after liming. Here in case of the cold sulphilation that is the acid sulphilation, we call it because the pH lower, in the second when it is along with the lime it is the alkaline sulphilation that is these are the other extraction, involve in case of the sugar refining.

(Refer Slide Time: 12:57)

Sugar Refining

- ❖ Affination: raw sugar mixed with saturated syrup and then centrifuged. Surface impurities are dissolve and removed
- ❖ Carbonation using milk of lime and CO_2
- ❖ Removal of impurities colour and impurities
- ❖ Sulphilation
- ❖ Cold Sulphilation(acid sulphilation at lower pH)
- ❖ Sulphilation after liming
(Alkaline sulphilation pH 7.5)

Because now, you seen the market wide variety of the sugar crystals available larger size, smaller size more whitish in nature, colorless even the in color also will find the different category of the and so, that that also the how the cost of the sugar that is fixed that is the purity of the product, color of the product larger size, lower size, smaller size of the crystal. So, for that the further refining that is very important.

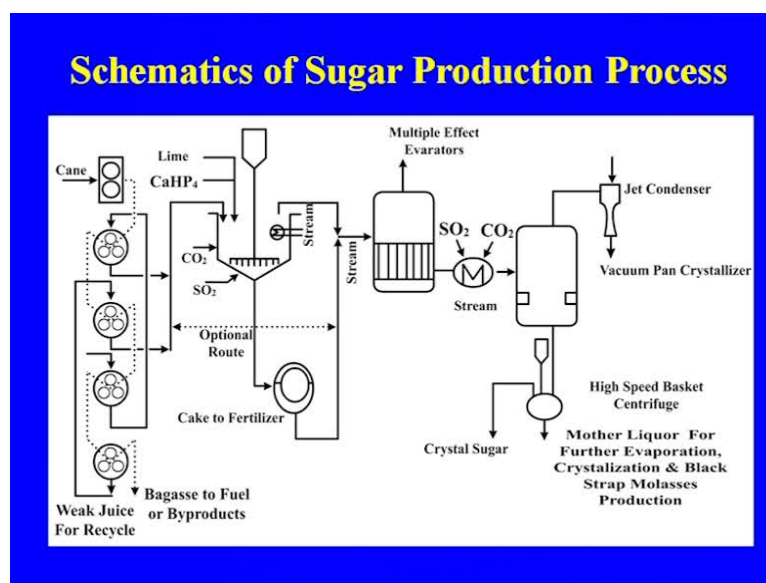

(Refer Slide Time: 14:25)

Sugar Refining

- Filtration
- Char filtration: activated charcoal for removal of impurities
- Crystallisation

So, what we are doing? Filtration, char filtration is where we are using the activated carbon for removal of the impurities, and then crystallization.

(Refer Slide Time: 14:36)

This is the flow diagram of the sugar manufacture of the cane sugar, cane that is going to the various crusher from where we are getting the juice, and that is going where we are adding the lime CO_2 , SO_2 and purification that is taking place and here we are that is going to separation, removal of the press mud from this. And so, after the filtration or through the washer, the cake is separated and the filtrate that is going to the multiple effective evaporator.

So, in the multiple effective evaporator, the juice is concentrated and the further refining again it is being done, and then the vacuum pan crystallizer we are using. And the finally, in the process we are getting the crystal sugar and the mother liquor for the further evaporation, crystallization and black liquor, strap molasses for the production of the alcohol. So, this is the flow diagram and the even here also the number of development that has taking place in case of the refining as I told.

Now, we are also using in addition to activated carbon ion exchange resin has been also used for the purification of the sugar, what are the major development has done. Because the one of the major problem that has been as you know that the recovery of the sugar that is decreasing especially, in the when at the last sixties of the sugar cane production means the, during the summer at the end of the around the March and April the so, recovery date goes on. So, what has been done in case of the sugar industry they have

continuously modified development that has taken place to increase the recovery of the sugar.

(Refer Slide Time: 16:47)

Development in Sugar Manufacture

- Installation of fiberliser: reduced energy in milling and increased extraction
- Increased number of rollers
- Reduction in crushing rpm of rollers
- Sulphilation
- Activated charcoal filtration
- Use of Ion exchange resin, hydrogen peroxide, Sugar Remelt Ion exchange Decolouristion Process

So, for that the new mills they are having the installation of the fiberliser, which is resulting in the reduce energy in milling, and increased extraction of the juice because that is very important, we cannot afford to lose the juice because if you are losing the juice it means, you are losing the sugar. So, increase the number of the rollers, so that the more and more milling and crushing that may be there, and extraction of the juice is more. Reduction in the crushing RPM of the roller, sulphilation process, activated charcoal filtration and then as I told you the use of the ion exchange resin, for the further purification hydrogen peroxide, sugar remelt ion exchange decolouristion process that has been added into some of the sugar mill, where they are extra purified sugar they are making.

These are the some of the commonly term used in the sugar industry that is the first, which I told you at the first step in case of the sugar manufacture; that is the milling process of extraction of juice from the sugar cane, breaks you need to used to express concentration of the sugar solution. This is the just to measure a the concentration of the sugar solution, which we are getting.

(Refer Slide Time: 17:48).

Commonly term Used in sugar industry

- **Milling:** Process for extraction Juice from sugar cane
- **Brix:** Unit used to express concentration of sugar solution
- **Bagasse:** Left after extraction of Juice from sugar cane
- **Press mud:** Waste after clarification of Juice
- **Defecation:** Process used for producing raw sugar

Bagasse that is left after the extraction of the juice from sugar cane, and this is also one of the very important bio-product of the sugar industry and normally, all the sugar industry they are using bagasse for the power generation in their bagasse based power boiler, but now there is in lot of discussion. Why not to use these bagasse for other purpose? Because you can produce paper from this, and let the other fuel be made available to the sugar industry.

So, that the more and more bagasse and that we are getting for the making of the paper another waste that we are getting from the during, the after the clarification of the juice that is the press mud waste after clarification of the juice, that we are getting that is containing line. Now, they have suggested because for making some of the bio fertilizer. So, press mud along with the concentrated waste from the memory separate process. They are mixing they are that is going for the composing. And defecation process is used for producing raw sugar, these are the some of the commonly term used.

Then the sulphilation purification using sulfur dioxide, carbonation and that term we are using purification using carbon dioxide. Massecuite the mixture of the sugar crystal syrup produced by crystallization. Molasses syrup of left after centrifuging, and separating sugar crystal, then the spent wash was after separation of the alcohol from the fermenter. Let us come discuss in more detail about the process step.

(Refer Slide Time: 19:16)

Commonly term Used in sugar industry

- Sulphidation: Purification using sulphur dioxide
- Carbonation: Purification using
- Massecuite: The mixture of sugar crystal and syrup produced by crystallisation
- Molasses: Syrup left after centrifuging and separating sugar crystal
- Spent wash: Waste after separation of alcohol from fermenter

(Refer Slide Time: 19:55)

Process Steps in Sugar Manufacture

- Sugar contains 70% water, 14% fibre, 13.3% succharose (about 10-15% sucrose) and 2.7% impurities. The yield of sugar depends mostly on the quality of cane and the efficiency of the extraction of juice.
- Crushing, milling and squeezing of juice through a series of pressure mills containing grooved walls Weak juice and make up water is added as extractant before squeezing to maximize juice yield.

As sugar contains 70 percent that is not sugar, sugarcane contains 70 percent of the water, 14 percent of the fiber, and 13.3 percent of the sucrose about 10 to 15 percent sucrose and this is the reason why normally, the recovery part which is there it is around 12 to 13 in most of the mills. So, if it is 12 to 13 it is sometimes it may be, but not more than and 2.7 percent impurity, the yield of the sugar depend mostly on the quality of the cane and the efficiency of the extraction of the juice. That is why I told you the milling process and extraction of the juice, and the installation of the faberizer that was the reason for going to increase the extraction of the juice.

Next step which I told you in this, when I summarize the that was the in this the abstract which I give you the about the various steps involved, that is the crushing milling and squeezing of the juice though a series of the pressure. Mill rolls containing grooved walls weak juice and makeup water is added as an extractant before squeezing just for the, to have more and more extraction that we are increasing, we are using the weak juice there.

(Refer Slide Time: 21:18)

Process Steps in Sugar Manufacture

- After crushing and extraction of juice, bagasse is left as residue which is about 33.3% of the total cane crushed. Bagasse is used as fuel for boilers.
- Purification of Juice for removal of impurities by addition of calcium phosphahate followed by addition of lime to precipitate the impurities in the form of colloid.

After crushing and extraction of the juice, bagasse is left as a residue, which is about 33 percent of the total cane crushed bagasse is used as a fuel for the boilers and the still. Whatever the bagasse, we are producing around 10 to 15 percent of the bagasse is surplus and that is being used by some of the paper mills, and number of paper mills based on the bagasse has come due to the increase in the production of the sugar cane. Purification of the juice of the removal of the impurities by addition of the calcium phosphate followed by addition of the lime to precipitate, the impurities in the form of the colloid because the purification parts also is that is very important, to get the good quality of the sugar crystal.

Then the evaporation and crystallization, the clarified juice is concentrated in the multiple effect evaporator to about 40 percent. And concentration, the concentrated syrup is again bleached by passing S O 2 through it. Concentrated sugar solution is then sent to the vacuum pan, where thickened syrup is boiled 3 to 4 times and then sent to the crystallizer, where separation of the sugar crystal takes place.

(Refer Slide Time: 22:14)

Evaporation and Crystallisation

- Clarified juice is concentrated in the in multiple effect evaporator to about 40% . The concentrated syrup is again bleached by passing SO_2 through it.
- Concentrated sugar solution is then sent to vaccum pan where thickened syrup is boiled three to four times and then sent to crystallizer where separation of sugar crystal takes place.

(Refer Slide Time: 22:43)

Purification

- Double carbonation using CO_2 and double sulphitation using SO_2 is used.
- The Clarified solution goes to evaporator and the underflow of clarifier goes to rotary filter for removal of the impurities as cake. The filtrate containing sugar from the rotary filter is recycled
- It is sent to high speed basket centrifuges for separation of sugar crystal .

Then comes the purification for arriving the double carbonation using CO_2 and double sulphonation using SO_2 . The clarified solution goes to evaporator and the under flow of the clarifier goes to the rotary filter, for removal of the impurities as cake which I told you the rotary filters, we are using the filtrate containing sugar from the rotary filter is recycled that is the filtrate, we are using during the extraction stage. Then it is sent to the high speed basket centrifuge, the concentrated of the purification for this separation of the sugar crystal.

(Refer Slide Time: 23:22)

Purification

- The syrup is reconcentrated and cooled successively to obtain one or two crops of crystal.
- The final mother liquor called molasses is sent to distilleries for production of alcohol by fermentation process where a counter current flow of water is used to remove sugar from beet slices.

The syrup is concentrated and cooled successively to obtain one or two crops of the crystal. The final mother liquor called the molasses is sent to the distillery for the production of the alcohol by fermentation process, where a counter current flow of water is used to remove the sugar from the beet slices, if you are using the beet.

(Refer Slide Time: 23:44)

By Product from sugar Plant

- Yield of various by products in % of cane crushed
- Bagasse 26 to 45%
- Press Mud
- 8.0-9.9 % in Double Carbonation
- 2.25- 4.9% Double sulphonation
- Molasses 3.27-6%

These are the some of the figures yield of the various product from the cane crushed bagasse press mud, and again the press mud that will depend up on the type of the

purification you are having whether, you are having the double carbonation or the double sulphonation and then the molasses.

(Refer Slide Time: 24:07)

These are the some of the waste product that we are getting from the, this is we start from the sugar cane, cane tops and the leaves that is the waste. And that can be used for making the compost, fuel, power generation, animal feed that is normally it is being used as a animal feed, but the dry part that can go that can be used for gasification also. Then the bagasse, which we are getting after the removal of the juice; then that is going to the bagasse fire boiler, bagasse fliers that can be used for the and bottom ash from the boiler that will go to the land fill and the bagasse, which is there that is having good amount of the carbon also, that can be used as a adsorbent or for making of the fire briquette.

Similarly, the other use of the bagasse that may be the as I told you the now the number of paper mills that has been they are using the bagasse as a raw material, and paper and board, news print also. Alpha cellulose, building composites along with the bagasse and some of the polymeric compound that you can make the building composites, domestic fuel furfural from the bagasse that is possible, poultry litter and the mulch composed wax animal feed, land fill and the fermentation industry, animal feed.

So, this is for the molasses that is an press mud that can because that can be some organic part is there that can be used as a fuel also, and that can be composed also because as I told you now, the because all the solid waste has to be utilized and. So,

along with the reject from the membrane separation process, they are making the compost also.

Now, let us discuss about the ethanol manufacture because you see the ethanol, that is one of the very important product of the. And many of the sugar mills they are integrating they are having the sugar production, as well as production of the ethanol. So, that is link, but many of the mills they are having the only the sugar making part and so, the molasses, which ever they are producing that is supplying and this is under control.

(Refer Slide Time: 26:39)

Ethanol

- India is amongst two largest sugar producing countries in the world and convert the molasses from sugar plant to alcohol.
- India is fourth largest producer of ethanol in the world and second largest in Asia.
- India produces about 2.75 billion alcohol annually The demand for potable alcohol has been ever increasing.

India is amongst the two largest sugar producing countries in the world, and convert the molasses from sugar plant to alcohol. India is the fourth largest producer of ethanol in the world and second largest in Asia. India produces about 2.75 billion alcohol annually liters that is the alcohol. The demand for potable alcohol has been ever increasing and the number of the your plants, which are making ethanol. They are also making the alcohol portable grade alcohol, apart from the industrial grade alcohol, which we are using.

(Refer Slide Time: 27:17)

Ethanol

- Today 95% of ethanol is produced by fermentation and only 5% is produced from petroleum feed stock by ethylene route.
- Ethanol has become one of the important product as alternative feed stock for large number of organic chemicals and fuel .
- Ethanol is an oxygenated fuel that contains 35% oxygen, which reduces particulate and NO_x emissions from combustion.

Today 95 percent of the ethanol is produced by fermentation, and only 5 percent is produced from the petroleum feed stock by ethylene route, because there are number of routes for ethanol is there, but the major production of the ethanol in India. And in some other part of the world, where the lot of the sugar is produced like Brazil and the other part of the world where the sugar cane production is more, it is the fermentation of the molasses that you are making the alcohol.

Ethanol has become one of the important product as alternative feed stock for large number of the organic chemicals, and fuel that will be discussed in lecture 2, while discussing the ethanol as the bio fuel and as the chemical feed stock. Ethanol is an oxygenated fuel that contains 35 percent oxygenation, which reduces the particulate and the N O X emission from the combustion and that is the reason why, that has been recommended blend of the alcohol along with the gasoline. Now, let us come to the historical review of the alcohol production.

(Refer Slide Time: 28:32)

Historical Review of Alcohol

- Beverage containing alcohol mentioned in ancient time back to Vedic period around 200B.C.
- Drinks: Soma and sura(fermented beverages)
- Alcohol was also used in many alcoholic preparation in tradition Ayurvedic

So, for the alcohol as a beverage is concerned that is mentioned in the ancient time, back to the Vedic period around 200 B C. Drinks soma and sura that was the fermented beverage and that has been mentioned in our religious books also. Alcohols are also used in the many alcoholic preparation, and the tradition Ayurvedic medicine also because that has been the part of the medicine also, the alcohol and now you will find the many of the syrup, cough syrups and all those they are containing some alcohol also.

(Refer Slide Time: 29:12)

Historical Review of Alcohol

- Fermentation of fruits to alcohol known to Primitive Humans
- Usage of beverages since ancient time and process of making beverages well established
- Period of colonial rule saw slow but steady rise in alcohol
- Development of Fermentation and production of alcohol from molasses started with development of sugar industry

Fermentation of the fruits to alcohol known to the primitive humans. Usage of the beverage since, the ancient time and process of beverage is well established that the smaller scale operation that was there earlier. Period of the colonial rule saw slow, but steady raise in the alcohol production. Development of the fermentation and production of the alcohol from molasses started with the development of the sugar industry, number of the sugar mills that increase and the production of the molasses was there, and the molasses was made available to the fermentation industry, for making the alcohol that we call will the distillery.

(Refer Slide Time: 29:56)

This is the various types of the drinks that we are having. So, for the portable gate of the alcohol is concerned a wide variety of the not only from the molasses route, but other routes are also there beet, sugar. All those thing they are also from the beet also we are making some of the grape of the fermentation of the some of the fruits also, we are doing and making good quality of the drinks.

(Refer Slide Time: 30:21)

Historical Review of Alcohol

- Foundation of the Scientific understanding: Louis Pasteur
- Further development in microbiology and Knowledge of microorganisms(Bacteria, yeasts and molds)and fermentation technology led to development of Alcohol Industry
- Production of lactic acid 1880
- The first distillery in India: At Kanpur in 1805 by Carew & Co Ltd

Foundation of the scientific understanding that was only after the Louis Pasteur, who developed the microbiology further, the development is microbiology and knowledge of the microorganism because we are using yeast here in the fermentation, and the fermentation technology led to the development of the alcohol industry. Production of the lactic acid that was in 1884 that is the. So, for the fermentation is concerned the first distillery in India was at the Kanpur in 1805 by Carew and the company that was in Kanpur.

(Refer Slide Time: 31:00)

Ethanol

- Alcohol is now being used for potable liquor, as chemical feed stock, as solvent and as oxygenates.
- Various routes for manufacture of ethanol
- ❖ Alcohol from Fermentation of molasses.
 - ❖ Alcohol from Lignocellulosic biomass
 - ❖ Alcohol from starchy feedstocks
 - ❖ Petrochemical route via catalytic hydration of ethylene and Ethylene esterification and hydrolysis.

Alcohol is now being used for the portable liquor, as chemical feed stock, as solvent and as oxidant various routes for manufacture of the alcohol because molasses is one route, molasses from the fermentation of the alcohol from the fermentation of the molasses. Alcohol from lignocellosic biomass because now, the lot of the work is going on also, this process from the biomass that was well developed earlier also, but there has been some problem in the pre treatment of the biomass.

And so, with the development of the pre treatment processes and the removal of the lignin, now it is considered as biomass that can be also a promising source, future source of the alcohol. Alcohol from the starchy feed stock petrochemical route were we are using the ethylene, and from the ethylene esterification and hydrolyzing various products that we can make.

(Refer Slide Time: 32:04)

Fermentation of Molasses

Molasses is the residue left after extraction of crystallised sugar and is one of the major byproducts of the sugar industry. Ethyl alcohol is made from molasses by fermentation process utilising yeast enzymes.

The molasses is the residue left after the extraction of the crystallized sugar, and is one of the major byproducts of the sugar industry. Ethyl alcohol is made from the molasses by fermentation process using the yeast enzyme. The various steps involved in case of the alcohol production that is the molasses handling, the molasses you are getting, because in many of the mills they are not having the fermentation plant, and there were alcohol production is not there. So, that is being some plight through the tanker to the different mills which are having your fermentation plant.

(Refer Slide Time: 32:49)

Steps in Fermentation of Molasses

- Molasses handling
- Fermentation feeding system
- Preparation of yeast inculam, propogation of yeast Fermentation
- Distillation of dilute alcohol for removal of impurities
- Further removal of water to make absolute alcohol

So, the molasses handling fermentation feeding system, preparation of the yeast inculam, propagation of the yeast from for fermentation distillation of the dilute alcohol for removal of the impurities because normally, in the fermentation. During the fermentation process, we are producing dilute alcohol and that alcohol that has to be concentrated, if you are interested for absolute alcohol, further removal of water to make the absolute alcohol or even anhydrous alcohol.

(Refer Slide Time: 33:34)

Fermentation of Molasses

- ❖ Molasses handling involves weighing of the molasses and pumping of molasses to the molasses tank from which the measured quantity of molasses is transferred to the fermenter.
- ❖ Preparation of yeast inculam, propogation of yeast: Yeast material is prepared in water cooled yeast vessels by inoculating molasses with yeast and then transferred to aerated yeast activation vessel to allow time for yeast cell multiplication.

Now, let us discuss the various steps in more detail the molasses handling involves weighing of the molasses and pumping of the molasses to the molasses tank, from which the major quantity of the molasses is transferred to the fermenter because that is a continuous process. Preparation of the yeast inculam, propagation of the yeast, yeast material is prepared in water cooled, yeast vessels by inoculating molasses with the yeast and then transferred to the aerated, yeast activation vessel to allow time for yeast cell multiplication and after that it is being added.

(Refer Slide Time: 34:05)

Fermentation of Molasses

- Fermentation involves fermentation of fermentable sugars by microorganism and formation of alcohol and other by products.
- Yeast (*Saccharomyces cerevisiae*) is commonly used for the fermentation of glucose to ethanol. After the fermentation alcohol of 7-8% strength is obtained. Fermentation is exothermic process and heat is generated.

(Refer Slide Time: 34:35)

Fermentation Of Molasses

- Removal of heat is necessary to maintain the temperature in fermenter. High temperature lowers the alcohol productivity. nutrients are added to the fermenter intermittently depending upon the requirement.
- Sulphuric acid is added to adjust the pH of fermenter liquid. Excess foaming in the fermenter is controlled by antifoam solution.

Fermentation involve the fermentation of the fermentable sugar by microorganism and formation of the alcohol, and other byproduct yeast is the commonly used for fermentation of the glucose to ethanol after the fermentation alcohol 7 to 8 percent strength is obtained, as I told you this is the we are getting the dilute alcohol. The fermentation is the exothermic process and heat is generated and so, continuous cooling has to be there during the process after C O 2 is removed.

And as I told you the removal of the heat is necessary to maintain the temperature in the fermenter. High temperature, lower the alcohol productivity nutrients are added to the fermenter intermittently, depending up on the requirement because all the micro process, if indeed the nutrient sulfuric acid is added to adjust the pH of the fermenter liquid. Excess foaming in the fermenter is controlled by antifoam solutions.

(Refer Slide Time: 35:05)

Fermentation of Molasses

- During the normal operation treated yeast cells recovered from the fermented wash are recycled from the yeast treatment system to activation vessel and after that transfers to the fermenter.

During the normal operation treated yeast cells recovered from the fermentation process are washed, recycled from the yeast treatment system to the activations vessel. After they transfer to again to the fermenter because one the growth of this yeast that has taken place then continuous, the process that is going on what about the yeast that is we are generating in the process that is again recycled.

(Refer Slide Time: 35:36)

Ethanol

- After fermentation is completed, the dil liquor (8-10% alcohol) is preheated and pumped to the beer still where the alcohol (50-60%) and other volatiles like aldehydes are distilled off from the top and sent to the aldehyde column for separation of aldehydes and other low boiling impurities.
- The residue from the bottom of the beer column is known as slops or stillage and is discharged and treated for recovery of energy or concentrated and used.

After the fermentation is complete the dilute liquor that may be, as I told you 7 to 8 percent or that will vary 8 to 10 percent alcohol is preheated, and pumped to the beer still where the alcohol of 95 and were the 50 to 60 percent. And other volatiles like aldehydes are distilled or from the top and send to the aldehyde column, for separation of the aldehyde this is the impurity that is the present, in the process and other low boiling impurities. The residue from the bottom of the column is known as slops, and stillage are discharged and treated for recovery of the energy or concentrated and used.

(Refer Slide Time: 36:23)

Manufacturing of alcohol

This is the reaction that is and during the process of alcohol manufacturing, lot of the CO_2 that is formed and that CO_2 some of the mills, they are also marketing, this CO_2 they are collecting, this CO_2 and that has been used for the various purposes, because it may be also used for making of the some of the useful chemicals.

(Refer Slide Time: 36:51)

Ethanol

- Alcohol drawn from side stream of the aldehyde column is sent to rectifying column. The azeotrop alcohol containing alcohol about 95-96% alcohol is taken as top side stream from the rectifying column.

(Refer Slide Time: 37:24)

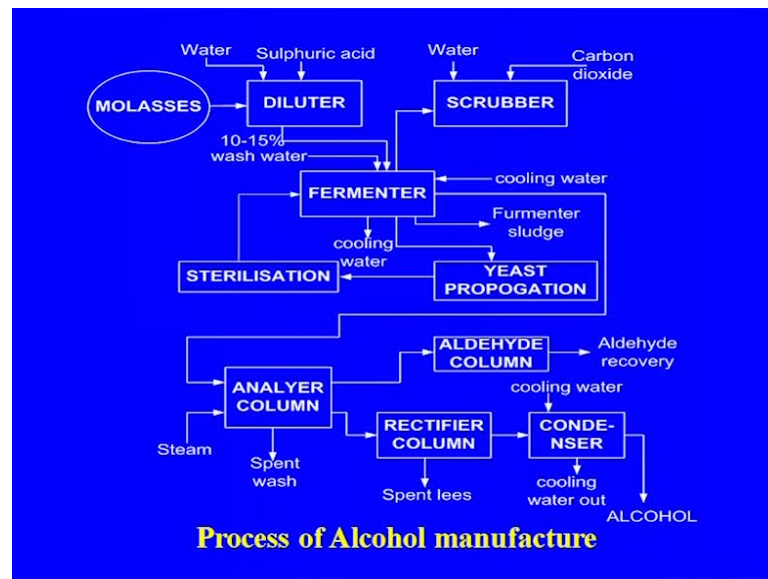

The alcohol drawn from the aldehyde column is sent to the rectifying column. The azeotrop because here the alcohol, and water that is the famous azeotrop that you are making, it is containing alcohol about 95 to 96. See it is taken as top side stream from the

rectifying column. So, that is the azeotropic mixture is there and azeotropic distillation is taking place to have the higher concentration.

This is the process you see the molasses, molasses it is going to fermentation process, it is going to distillery and then, the final products ethanol that you are getting.

(Refer Slide Time: 37:31)

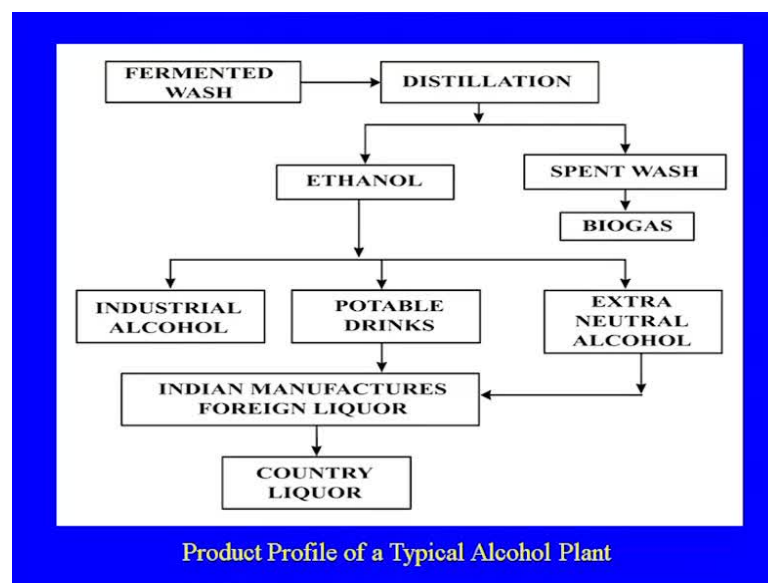

This is the in detail about the process, which I discussed. Molasses it is going to be the diluter where we are adding the sulfuric acid and after the sulfuric acid, it is going to the fermenter, fermenter this is what I was telling this CO_2 , CO_2 that is going to the scrubber after there is a carbon dioxide, this is going outside from this cover. The fermenter after the fermentation, we are getting the here the because the from the fermenter, fermenter sludge will be also there and your alcohol, dilute alcohol that is going to the further concentration yeast.

Again as I told you the yeast, which is produced during the process that is also multiplication of these it is there. And so the yeast of distraction again it is going to fermenter after that what is do the analyzer column, where we are concentrating further concentrating the alcohol. So, a spent wash is used, what is that spent wash? That is a very useful byproduct in case of the alcohol, and this is being used and this is having very high C U D 1 lakh.

So, that is the sometime problem also if you are not using the properly this spent wash. And so, they are generating the anaerobic treatment of the spent wash that are generating. And so, this is what we are doing in case of the sugar industries were they are having the sugar and alcohol both. So, the treatment process first it is the utilization of the spent wash in the anaerobic treatment process to produce the a methane gas, which is being used as the whatever, the gases there are that is being used for the power generation that is being using the industry.

And then the what about the spent wash after the even anaerobic treatment that is containing, you can say around 500 to 10,000 C U D still highly colored material that you are getting, after the anaerobic treatment. So, lot of the challenges the distilleries are facing, how to further treat this spent wash, which you are getting after the anaerobic treatment because that is highly colored, and the C U D load is very high. Some of the places they have because normally in some of the country, what they are doing the treatment of this spent wash.

(Refer Slide Time: 41:12)

Before going it is going to anaerobic treatment, they are doing the pre treatment and in our country what we are doing, we are using this spent wash for the power generation and then it is going for the further treatment. Finally, we are getting the alcohol. You see as I told you, this I will be discussing in detail while in the lecture 2 that the, what are the different byproduct that you are getting the molasses? How to utilize the molasses and

they are converting? This alcohol molasses to alcohol and alcohol to ethanol and that ethanol that is being used for manufacture of large number of the product, this is the actually the flow diagram of the various product that is one of the molasses based chemical plant.

This is the product profile of the ethanol that is the fermented wash, distillation. So, we are getting the ethanol, spent wash that is going for the biogas generation, which I am telling after the biogas generation, whatever the effluent that you are generated that is going to the further treatment. Now, the centre portion control board they are very much concerned about the distillery because that is one of the highly polluting industry. So, the different type of alcohol, which we are getting that may be industrial alcohol, portable alcohol and so, that may be the extra neutral alcohol, country liquor although thing that is the various type of the product that you are getting.

(Refer Slide Time: 42:00)

Alcohol Recovery

- **Alcohol Recovery:** this section involves the recovery of alcohol from the fermentation section to minimize the possible losses of alcohol along with generated CO₂ and sludge from fermented.
- Typical reactions involved are
- $C_{12}H_{22}OH + H_2O \longrightarrow C_6H_{12}O_6 + C_6H_{12}O_6$
- Molasses \longrightarrow Glucose + Fructose
- $C_6H_{12}O_6 \longrightarrow C_2H_5OH + 2CO_2$

Alcohol recovery that is very important in case of the your alcohol plant. So, this section involves the recovery the alcohol from the fermentation section to minimize, the possible loss of the alcohol along with the generated C O 2, and sludge from the fermenter. Another thing that let us discuss because that was one source and now, the lot of the work that is going on for the production of the alcohol, ethanol forming biomass because the biomass gasification. We discussed earlier while discussing the coal and biomass

gasification, but another thing that we are interested in utilization of the biomass just for the production of the alcohol.

(Refer Slide Time: 42:46)

Alcohol from Biomass

- Technologies for producing ethanol from cellulosic biomass through fermentation and chemical hydrolysis have been developed from Lab to commercial scale. globally, if even 10% of biomass is used for fuel production there may be substantial reduction in oil consumption.
- Ethanol thus produced can be a promising chemical feed stock.

So, technology for producing ethanol from the cellulosic biomass through fermentation and chemical hydrolysis, have been developed from lab to commercial scale. Globally even if 10 percent of the biomass is used for the fuel production, there may be substantial reduction in the oil consumption. So, it is being considered the future raw material for the chemical plant as well as, as a source of the fuel.

Ethanol thus because the gasification route that is one route, that can be the gasified gas that can be used for the making the that can be synthesis gas that can be as fuel, or making of the by these chemicals also another route that is the what, we are having the alcohol from the biomass. So, there may be substantial reduction because that will provide alternative source of the fuel ethanol. Thus produce can be a promising chemical feed stock also.

(Refer Slide Time: 43:53)

Alcohol from Biomass

- US based Primus green Energy has developed a high conversion efficiency biomass to gasoline process based on innovative thermal chemical conversion and the process can generate 416 litres of gasoline per tonne of biomass.
- Lignocellulosic biomass, is available abundantly and can be used as the alternative feed-stock for bioethanol production.

U S based primus green energy has developed a high conversion efficiency biomass to gasoline process based on the innovative, thermal, chemical conversion and the process can generate 416 liters of the gasoline per ton of the biomass. Lignocellulosic biomass, is available abundantly and can be used as the alternative feed stock for ethanol production. Alcohol from the biomass, what are the process that is involved in case of the when we are using the biomass because from you see the during the 30, 40 also the lot of the work that was done for the making of the lingo, but the micro biology that was not well developed.

(Refer Slide Time: 44:58)

Alcohol from Biomass

- Lignocellulosic biomass includes forest residues such as wood; agricultural residues such as sugarcane bagasse, corn cob, corn stover, wheat and rice straw; industrial residues such as pulp and paper processing waste, lignin from pulp and paper mills and municipal solid wastes, and energy crops such as switch grass.
- These have the potential for use as feed-stock for the production of fuel ethanol

The pre treatment process were not well developed and so, the real actually the work that was started for making of the alcohol from the biomass, with the development of the pre treatment technology, and the processes for the removal of the lingo. So, lingo cellulosic biomass includes forest residue such as wood, agriculture residues such as sugar cane bagasse, corn cob, corn stovers, wheat and rice straw industrial residues, such as pulp and paper processing, waste lignin from the pulp and paper mills and municipal solid waste and energy crops such as the grasses.

(Refer Slide Time: 45:42)

Alcohol From Biomass

- The nature and availability of lignocellulosic feed-stocks in different parts of the world depend on climate and other environmental factors, agricultural practices, technological developments.

(Refer Slide Time: 45:57)

Alcohol from Biomass

Advantage of lignocelluloses for ethanol production:

- To a larger extent, locally/domestically and provide security of supply.
- Generate low net greenhouse gas emission, reducing environmental impacts, particularly climate change.
- Also provide employment in rural areas.

So, this is the actually the some of the biomass general term we are using for biomass for these waste material, these have the potential for the use as a feed stock for the production of the fuel and ethanol. The nature and availability of the lingo cellulosic feed stock in the different parts of the world depend on the climatic condition another environmental factor, agriculture practices, technological development.

Advantage of the lingo cellulosing material to a larger extent locally, domestically and provide security for the supply. Generate low net greenhouse gas emission, reducing the environmental impact, particularly the climatic change that we are having because of the deforestation because of using of the natural resources. Also, the providing employment in the rural area.

(Refer Slide Time: 46:24)

Composition of common agricultural residues and wastes-			
Agricultural residue	Cellulose (%)	Hemicellulose (%)	Lignin (%)
Hardwood stem	40–50	24–40	18–25
Softwood stem	45–50	25–35	25–35
Nut shells	25–30	25–30	30–40
Corn cobs	45	35	15
Grasses	25–40	35–50	10–30
Wheat straw	33–40	20–25	15–20
Rice straw	40	18	5.5
Leaves	15–20	80–85	0
Sorted refuse	60	20	20
Cotton seed hairs	80–90	5–20	0

This is the cellulosic content of the various raw material hardwood, softwood, nutshells corn cobs, grasses, wheat straw, rice straw, cellulose contain hemicelluloses. This lignin that is creating problem in utilization of the biomass for the alcohol purpose. Otherwise, if so for the bio gasification, you concern no problem and at the same time use of the these biomass for the production of the paper, again that will depend up on the cellulosic content of the your biomass.

(Refer Slide Time: 47:06)

Agricultural residue	Cellulose (%)	Hemi cellulose (%)	Lignin (%)
Coastal Bermuda grass	25	35.7	6.4
Switch grass	30–50	10–40	5–20
Solid cattle manure	1.6–4.7	1.4–3.3	2.7–5.7
Swine waste	6.0	28	
Primary waste water solids	8–15	NA	24–29
Paper	85–99	0	0–15
Newspaper	40–55	25–40	18–30
Waste paper from chemical pulp	60–70	10–20	5–10

Source; Bhoopathy,1998, Cheung. and Anderson 1997.

This is again some of the agricultural residue that you are getting.

(Refer Slide Time: 47:10)

Bio-ethanol from Biomass

TECHNOLOGIES:

- Concentrated acid hydrolysis
- Dilute acid Hydrolysis
- Enzymatic Hydrolysis
- Biomass gasification and fermentation
- Source: Biofuel 2003

Technology bio-ethanol from the bio-mass, what are the technology available? The concentrated acid hydrolysis, dilute acid hydrolysis enzymatic because of coming of the enzyme bio-technology, lot of the improvement in the hydrolysis process that has taken place biomass gasification in the fermentation. Biomass gasification, already we have discussed this is the fermentation process, from where you can get the alcohol there, it will be the bio gasification to your synthetic gas, synthetic gas to methanol and that

methanol again that can be used for the making of the bio-fuel, this is the ethanol production per ton of the product, di-product from the various sources.

(Refer Slide Time: 47:59)

Potential For Ethanol From Cellulosic Matter

Feed stock	Gallons Ethanol per tonne
Bagasse	112
Rice straw	110
Forest thinnings	82
Hardwood dust	101
Mixed Paper	116

Bagasse, rice straw, forest thinning, hardwood dust and the mixed paper.

(Refer Slide Time: 48:06)

Cellulose, Hemicellulose and Lignin in Biomass

Component	Percent dry weight
Cellulose	40-60
Hemicellulose	20-40
Lignin	10-25

This is the cellulose, hemi cellulose and lignin in the biomass and that is the 40 to 60 percent, 20 to 40 percent hemi cellulose and lignin 10 to 15, 25 percent. Disadvantage of ethanol because there has been lot of discussion for ethanol as a bio-fuel, again that will be discussed by discussing the importance of the ethanol as a bio-fuel, but these are the

some of the disadvantages, which has created problem in utilization of the ethanol as a bio-fuel.

(Refer Slide Time: 48:44)

Disadvantage of Ethanol as Biofuel

- Higher aldehyde emissions
- Corrosiveness, affecting metallic part
- Higher latent of vapourisation
- Higher evaporation losses due to higher vapour pressure
- Requiring large fuel tank due to lower calorific value
- Below 10% disadvantages are not serious
- Source[Biofuel 2003]

Higher aldehyde emission, corrosiveness, higher latent of vaporization, higher evaporation loss, requiring large fuel tank to lower the calorific value below 10 percent due to a disadvantage are not serious because normally, it tells the reason. Why 5 to 10 percent blending of the ethanol that has been recommended?

(Refer Slide Time: 49:06)

Bio-ethanol from Biomass

- The degree of complexity and feasibility of biomass to ethanol depends on the nature of feed stocks
- Lignin remains a residual material after the sugars in biomass have been fermented to ethanol

The degree of the when you are going for the bio-ethanol from the biomass, the degree of complexity and feasibility of the biomass to ethanol depends on the nature of the feed stock. As I told the contents of the, because the variation in the composition of the biomass is there, lignin remains a residual material, after the sugar in biomass have been fermented to ethanol. That lignin evens the separation of the lignin that is creating problem in case of the utilization of biomass. Already we have discussed these are the some of the technology that is available.

(Refer Slide Time: 49:54)

Process Technology

All conversion schemes involves following basic steps:

- ❖ Feedstock harvest, transport and storage.
- ❖ Pretreatment of lignocellulosic biomass.
- ❖ Enzyme hydrolysis of cellulose in the lignocellulosic materials to fermentable reducing sugars.
- ❖ Fermentation of sugar into ethanol.
- ❖ Downstream processing of ethanol.

All the conversion processes in case of the biomass to ethanol that contains the feed stock harvesting, transport and storage pretreatment of the lingo cellulosic biomass, enzyme hydrolysis of the cellulose in the lingo cellulose material to fermentable reducing, sugar fermentation of the sugar into ethanol downstream processing of the ethanol. So, these are the some of the steps involved in case of the when you are going for manufacture of the ethanol from biomass. So, as I told you the pretreatment that is one of the problem in case of the, but that is pre requisite without that you cannot go for the further other process, which involve in case of ethanol process.

(Refer Slide Time: 50:38)

Alcohol from Biomass

Pretreatment of biomass is a prerequisite to the biological conversion of lignocellulosic biomass to ethanol.

Pretreatment is done either physically, chemically or biologically to make pretreated biomass more amenable to subsequent cellulose hydrolysis. Pretreatment alters the size and structure of the biomass as well as chemical composition.

So, the pretreatment of the biomass is a prerequisite to the biological conversion of the lignocellulosic biomass to ethanol. Pretreatment is done either physically, chemically or biologically to make the pretreated biomass more amenable to subsequent cellulose hydrolysis. Pretreatment alters the size and structure of the biomass as well as chemical composition because these are some of the factors that will decide, that will the pretreatment impact of the that will be that will alter the size. The structure of the biomass, as well as the chemical composition because some of the impurity that will be removed, during the pre treatment process. This already I have discussed in the, I have summarized.

(Refer Slide Time: 51:34)

Alcohol from Biomass

- Ethanol from cellulosic material is produced either by acid hydrolysis using sulphuric acid or enzymatic hydrolysis.
- Both dilute and concentrated sulphuric acid are used in acid hydrolysis.

The various steps involved in case of the alcohol that is the cellulosic material, which produce either by acid hydrolysis using sulphuric acid or enzymatic hydrolysis. Both the process that is available, both the dilute and concentrated sulphuric acid are used in the acid hydrolysis.

(Refer Slide Time: 51:46)

Alcohol from Biomass

- Dilute sulphuric acid involves milder condition than concentrated sulphuric acid hydrolysis. In acidic hydrolysis first converts cellulosic materials to sugar followed by conversion of sugar to other chemicals.

Dilute sulfuric acid involved milder condition than the concentrated sulfuric acid hydrolysis. In acidic in acidic hydrolysis, first convert cellulosic material to sugar followed by the conversion of sugar to other chemicals.

(Refer Slide Time: 52:02)

Alcohol from Biomass

- Enzymatic hydrolysis of cellulose another route for alcohol.
- Enzymatic processes requires pretreatment of lignocellulosic to break the crystalline structure of lignicellose and remove the lignin to expose the cellulose and hemicelluloses .
- Depending on the biomass material physical or chemical pretreatment methods may be used.

Enzymatic hydrolysis of the cellulose another route for alcohol, enzymatic process requires pretreatment of lignin cellulose to break the crystalline structure of the lignicellose, and remove the lignin to expose the cellulose and hemicelluloses, because this is the reason. Why the lignin removal? That has been very important. Depending on the biomass material physical or chemical pretreatment methods may be used.

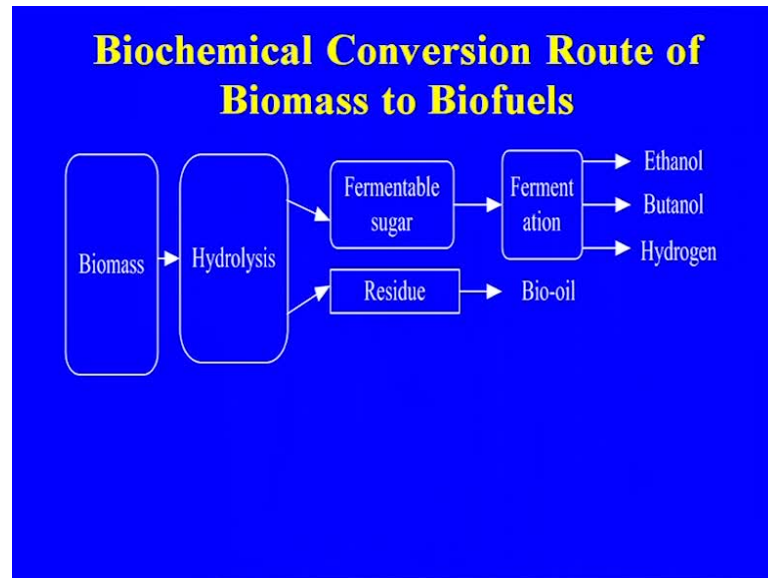

(Refer Slide Time: 52:30)

Alcohol from Biomass

- Pretreatment
- Physical method may use high temperature and pressure, milling, radiation or freezing.
- The chemical method uses a solvent to break apart and dissolve the crystalline structure.

So, as I told you the physical treatment method may use high temperature and pressure, milling, radiation or the freezing. Chemical methods use a solvent to break apart and dissolve the crystalline structure.

(Refer Slide Time: 52:44)

This is the actually the steps involved biomass, it will go to the hydrolysis fermentable sugar and then the residue and then the fermentation process, ethanol, butanol or the hydrogen whatever the product that what have.

(Refer Slide Time: 53:00)

Alcohol from Biomass

Technological Barriers: Some of the technological barrier which needs to be addressed in efficient conversion of biomass to ethanol are

- Pretreatment,
- Sachatification of cellulose and hemicelluloses matrix
- Simultaneous fermentation of hexose and pentosone sugars.

Technological barriers. Some of the technology barriers, which need to be addressed in the efficient conversion of the biomass to ethanol or the pretreatment saccharification of the cellulose and the hemicellulose matrix. Simultaneous fermentation of the hexose and pentose sugar. These are some of the technological barriers.

(Refer Slide Time: 53:20).

Alcohol from Biomass

All conversion schemes involve following basic steps:

- Feedstock harvest, transport and storage.
- Pretreatment of lignocellulosic biomass.

All conversion schemes involve following basic steps already I discussed the feed stock, harvesting pretreatment and then finally, the hydrolysis. So, this is how we can have an alternative source of ethanol from biomass. In the next lecture, lecture 2 we will be discussing about ethanol in more detail about how ethanol can be used for the production of various useful chemicals. And that is being used in many of the plants, some are integrated and in some cases they start from fermentation and then the ethanol is being used for the manufacture of a large number of chemicals.

And one of the reasons even the starting of some of the chemicals that was through the ethanol route not it was the petroleum route. But it was the ethanol route as some of the examples are Indian glycol, various organic which are now synthetic chemicals barely and some of the other plants, Sumitomo chemicals all are they were using the alcohol for producing a large number of chemicals, which are now being made from the petrochemical route.
